# INAF

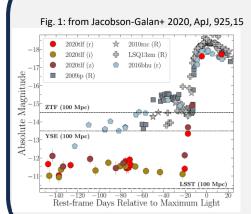

### **GalRSG:**

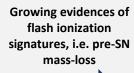

## A long-term monitoring campaign of Galactic Red Supergiants and the quest for SN premonitory signs (See poster S1.1)

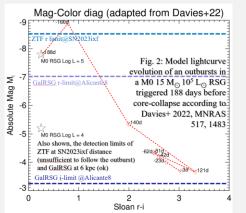

F.Bocchino, S. Orlando, M. Miceli, O. Petruk, A. Pastrorello, M. Limongi, A. Chieffi, G. Peres

### 1. Pre-SN outbursts: focus on low-mass RSGs

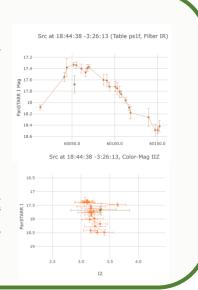

### 3. The monitoring campaign

- Higher sensitivity allows us to target mid/low-L RSGs (i.e. the majority) and their precursors.
- Multi-band optical/NIR homogeneous coverage
- Short and regular cadence (<= few days).
- No need of large telescopes. Now using INAF-REM & INAF-VST
- **Duration** => 3 yr
- Other current surveys either have too-long cadence or lack of iz/NIR colors. LSST baseline survey has too-long cadence
- GalRSG lightcurve database has a legacy value

### 2. The sample of Galactic Red Supergiants

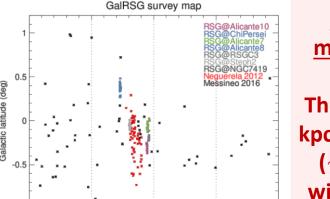

**BEFORE** 

I look for as many **SNe** as possible THEN I maybe detect a **precursor**  HERE COMES GaIRSG

I monitor as many 7-15 M<sub>☉</sub> **RSGs** as possible THEN I maybe detect a **SN** 

Galactic longitude (deg)

Scutum-Crux massive clusters

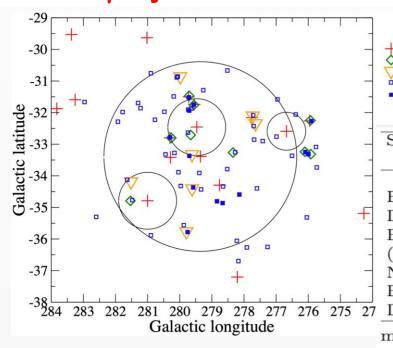

They are all at  $\sim 6$  kpc, approx. coeval ( $\sim 15$  Myr) and within few deg in the sky

# Search for $\gamma$ -ray emission from SNRs in the Large Magellanic Cloud: preliminary results of a new cluster analysis at energies above 4 GeV

A.Tramacere, R.Campana, E.Massaro, F.Bocchino, M.Miceli, S.Orlando

### See poster S1.2

We applyed two cluster search methods (MST and DENCLUE) for detecting photon concentrations in the 15 y Fermi-LAT field of LMC. Confirm of 9 previous detections and slection of 6 new γ-ray SNR candidates.

# Gamma-ray detection of newly discovered Ancora supernova remnant: G288.8–6.3

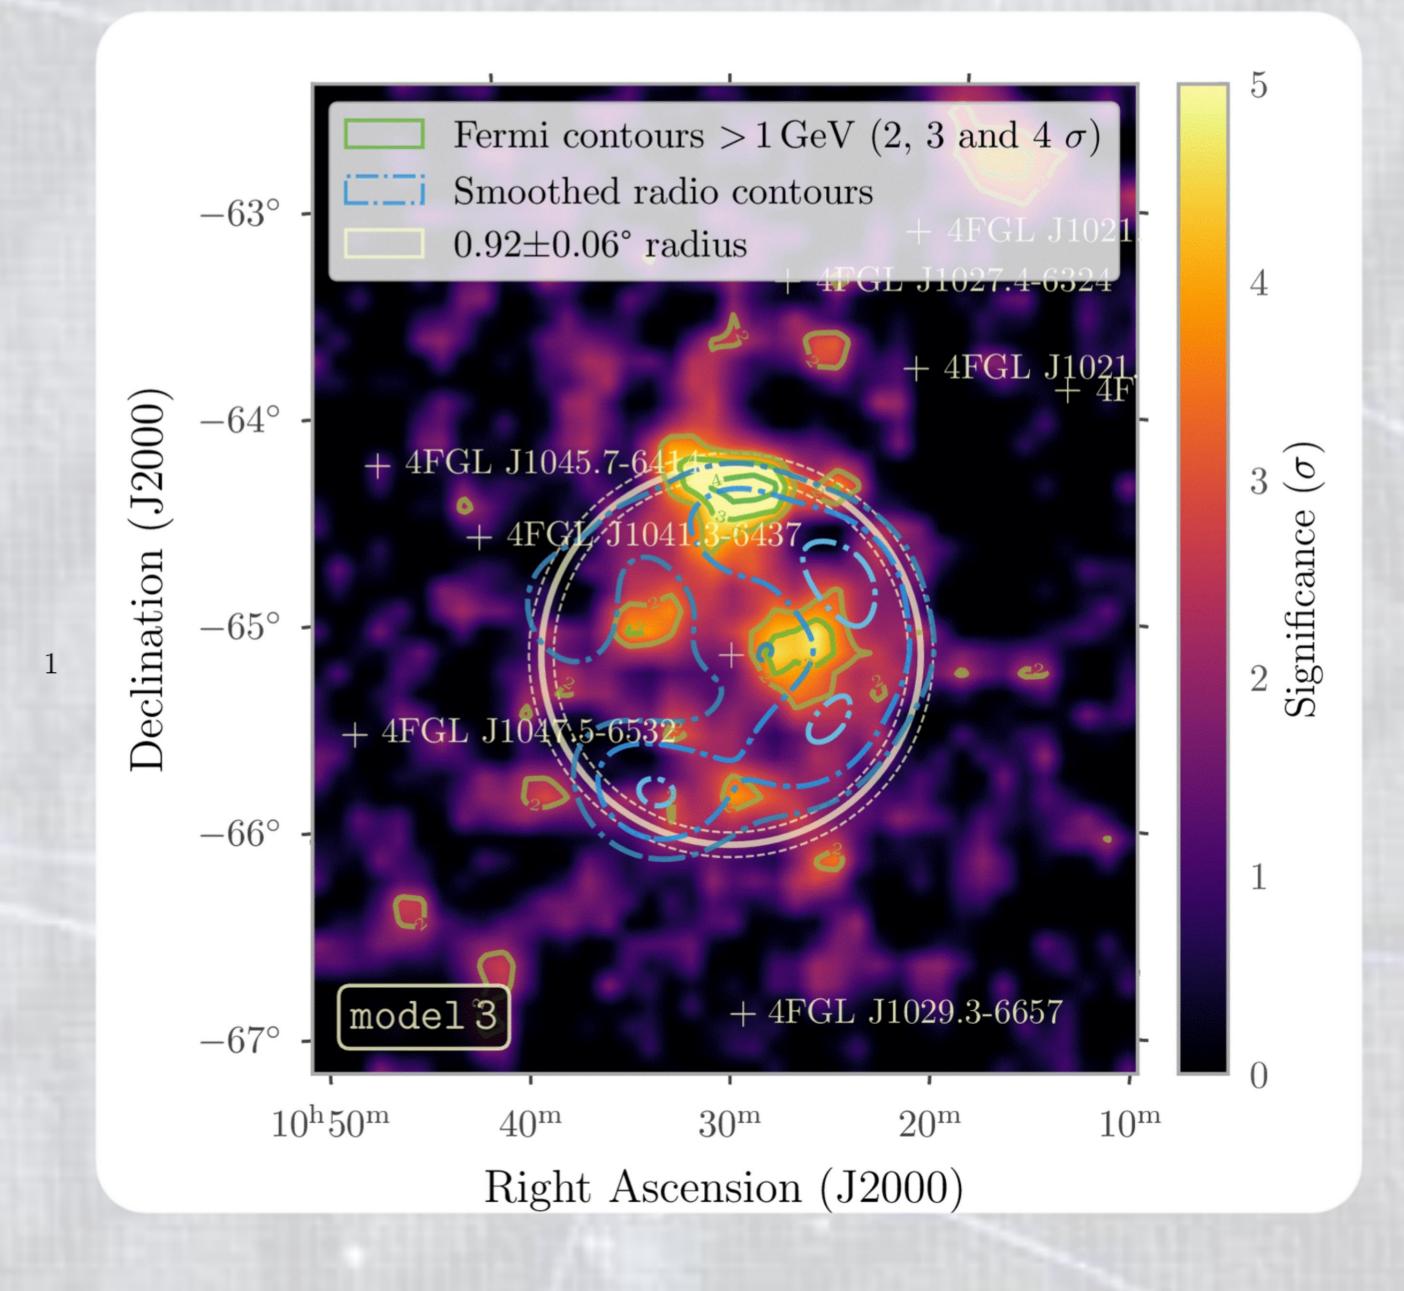

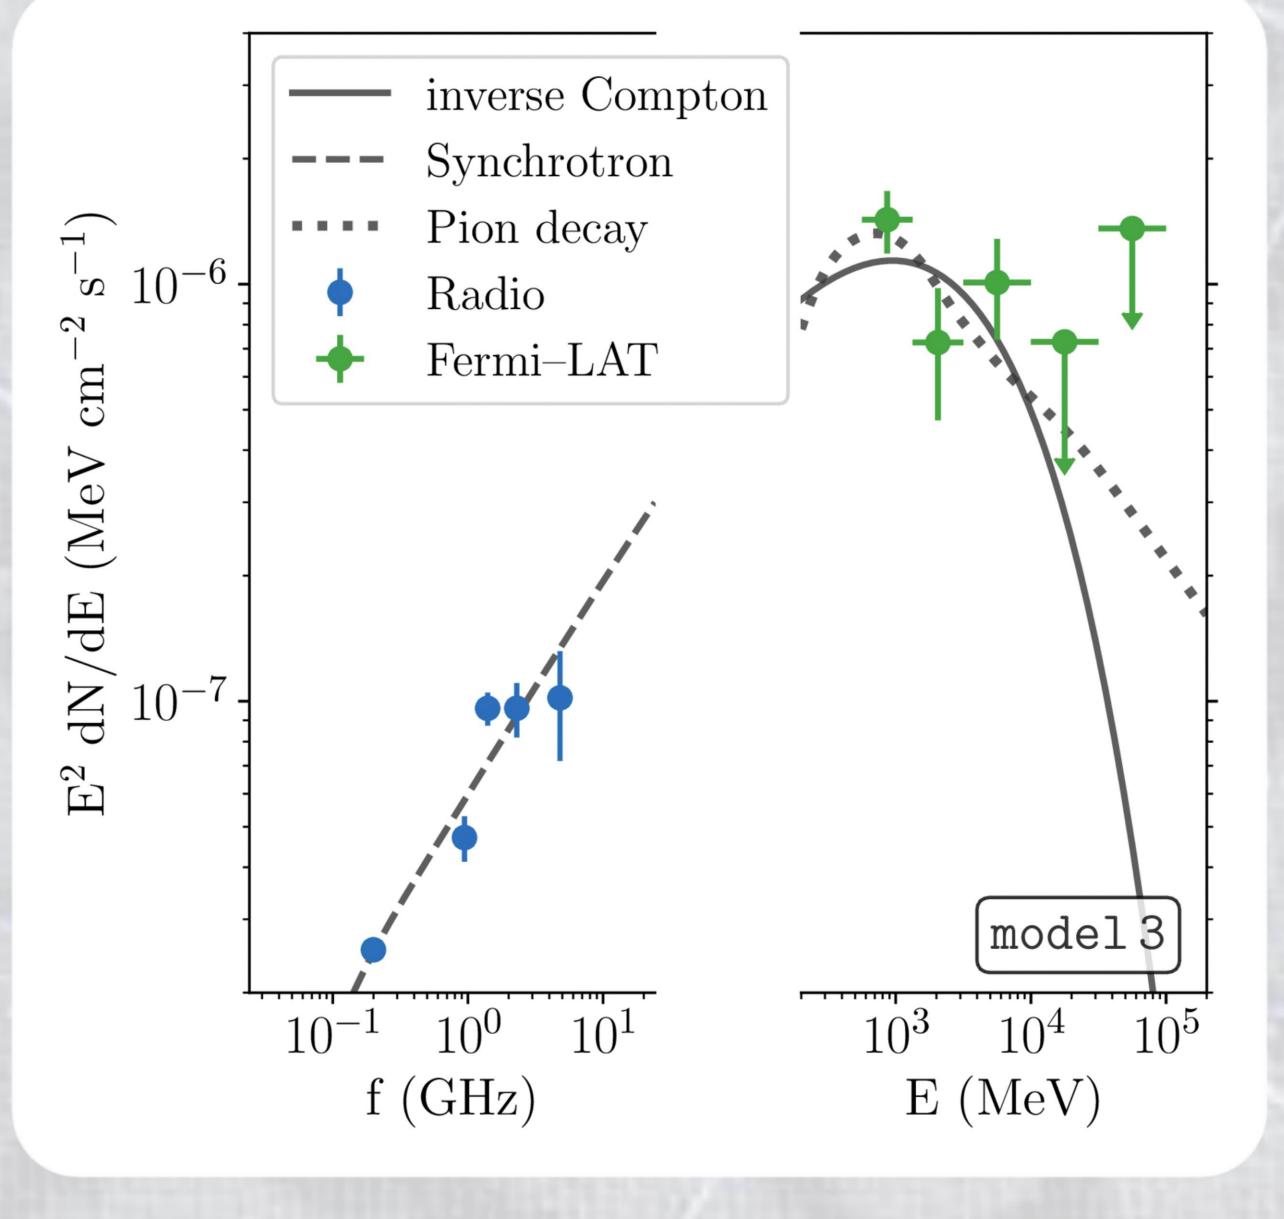

cburger@cp.dias.ie

Christopher Burger-Scheidlin (Dublin Institute for Advanced Studies DIAS)

# Ancora SNR.

- Recently discovered at high Galactic latitude using observations with ASKAP (Filipović et al. 2024)
- Fermi-LAT detection of extended emission with up to 8.8  $\sigma$  using a Disk/PL model (energy flux of (4.80  $\pm$  0.91)  $\times$  10<sup>-6</sup> MeV cm<sup>-2</sup> s<sup>-1</sup>)
- Spectrum up to 5 GeV, hotspots above 1 GeV, s=2.3 ± 0.11
- One of only seven objects at high Galactic latitude detected with Fermi-LAT
- Study of this new population of remnants in such unperturbed environments can provide insight into the evolution and properties of SNRs

### Galactic SNR catalogues: since 1984

Dave Green: dag9@cam.ac.uk
University of Cambridge

https://www.mrao.cam.ac.uk/surveys/snrs

New version later this year. What has changed since the first version.

1. The number of SNRs has more than doubled: (145 in 1984 version, now 310 entries)

→ this is good!

2. Many more distances are available: (so no longer dependant on ' $\Sigma - D$ ' relation, which is not reliable)

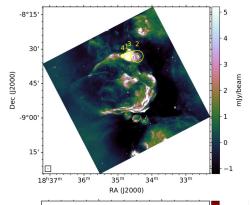

→ this is good!

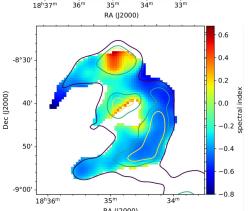

3. Selection effects are still a big problem for statistical studies: (faint SNR are missing, especially towards  $l = 0^{\circ}$  and  $b = 0^{\circ}$ ; young but distant (i.e. small angular size) SNRs are missing; many possible/probable remnants still need clarification)

→ this is not good!

I. Leonidaki <sup>1,2</sup>, A. Zezas <sup>1, 2</sup>, K. Anastasopoulou <sup>3</sup>, M. Kopsacheili <sup>4</sup> and P. Boumis <sup>5</sup>

# MOTIVATION

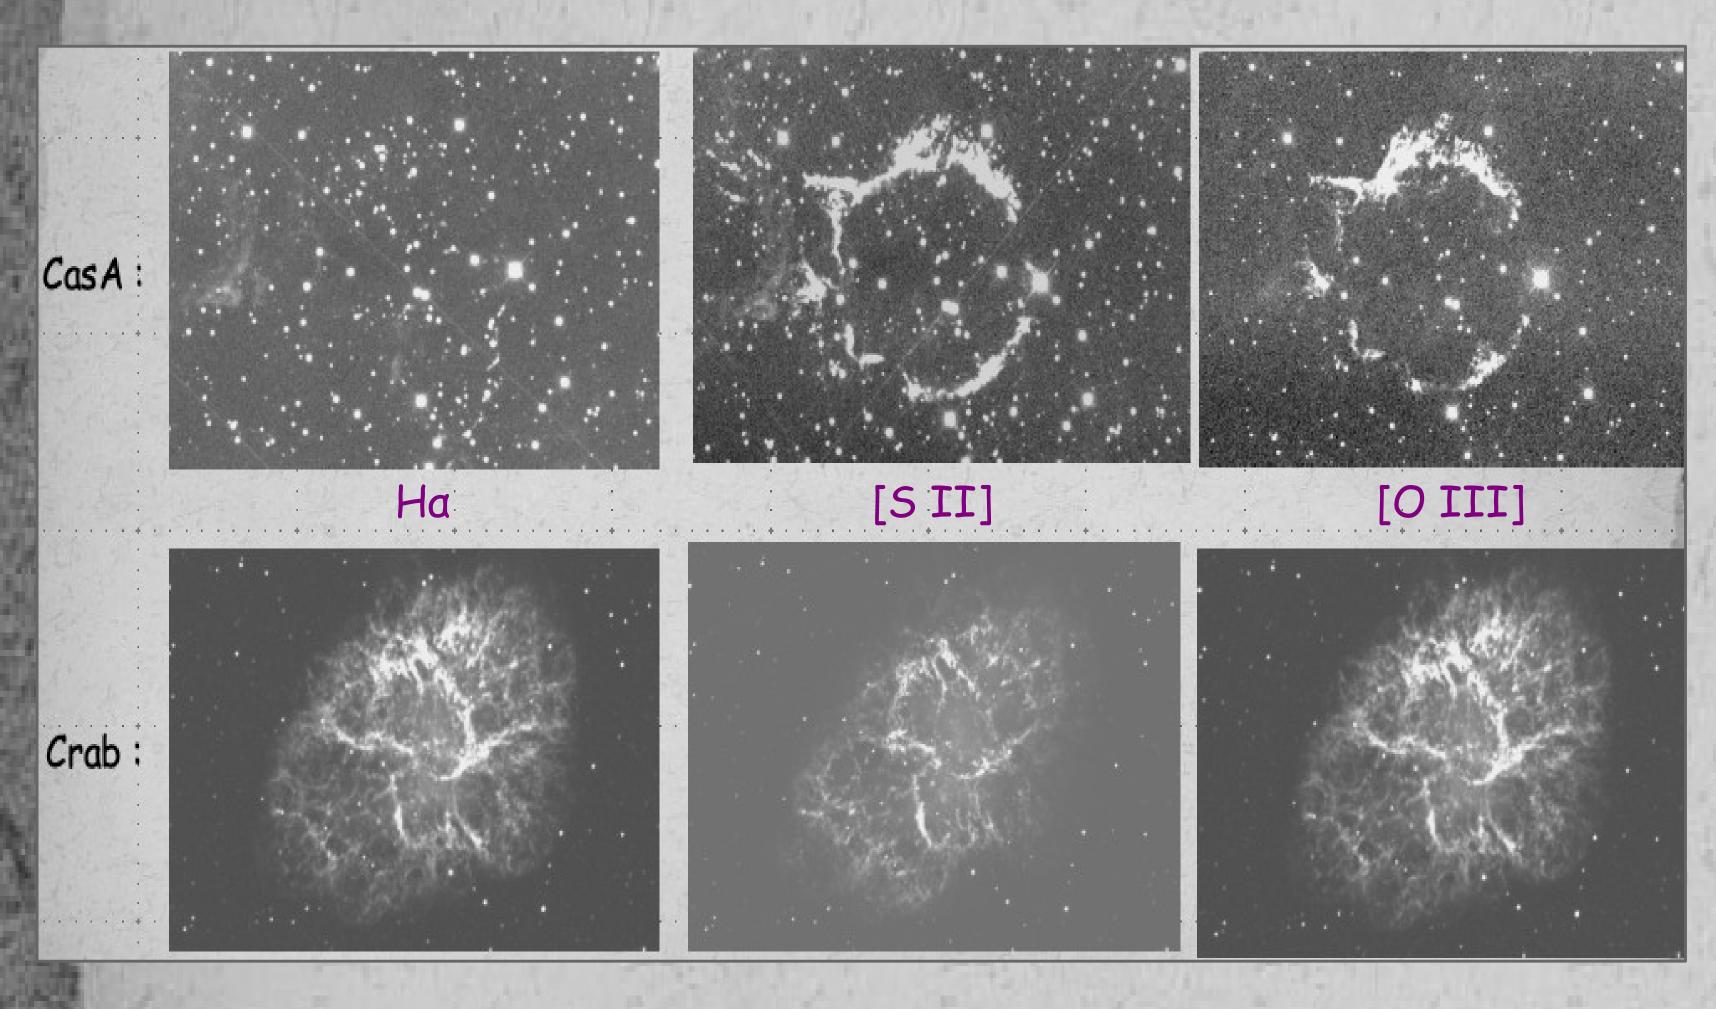

- Provide for the first time an observational framework for understanding the evolution of SNRs based on the Galactic SNR population
- Investigate SNR evolution through multi-wavelength emission as a function of age and environment
- Test theoretical models.

# OBJECTIVE

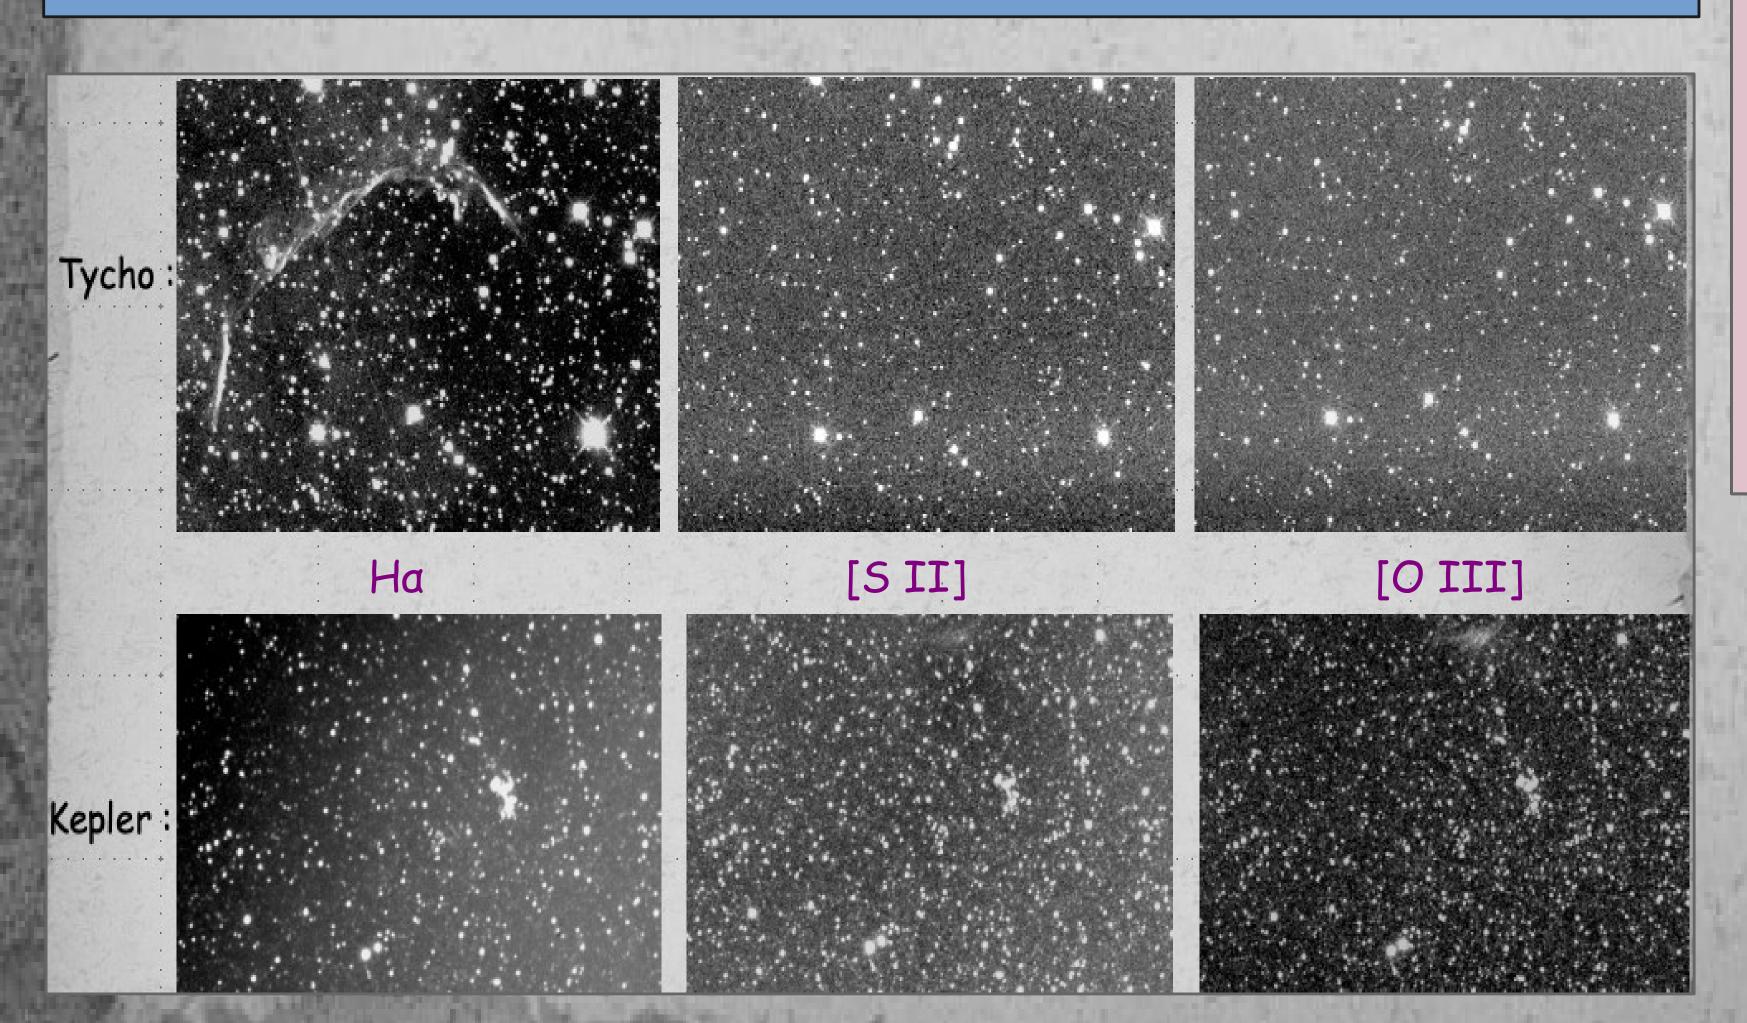

Optical coverage of all Galactic SNRs in narrow-band filters of SNRs' interest (i.e. Ha, [S II], [O III], Hß) since despite the wealth of data, only ~35% of Galactic SNRs had been observed in the optical band so far.

The presented sample is the first of a series dealing with the <u>optical study</u> of X-ray emitting, Galactic SNRs (29 objects)

# RESULTS

(Leonidaki et al., submitted)

•Integrated Ha, [S II], [O III] fluxes.

 Only 5/29 of the X-ray emitting SNR sample emit in the optical

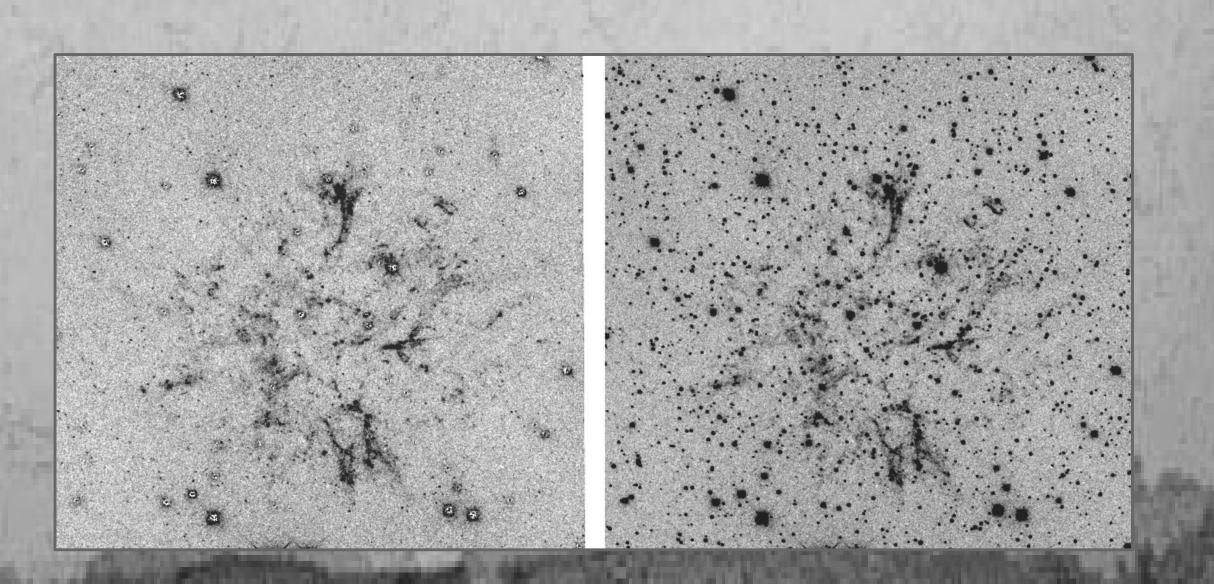

Tycho Kepler CasA 3C58 Crab

Type Ia Type IIb Plerionic

Binary systems / massive progenitors

Dense stellar winds and/or wind-driven bubbles modify/transform substantially the CSM

Possible explanation of optical emission in young SNRs (?)

### A systematic meta-analysis of physical parameters

of Galactic supernova remnants

I. Chousein-Basia, A. Zezas, M. Kopsacheili, I. Leonidaki

### What did we do?

Collection and analysis of electron density, shock velocity, and age data from published studies for 63 Galactic SNRs.

### Why?

No systematic analysis on the properties of Galactic SNRs.

### What methods did we use?

A personalized data homogenization technique, i.e. Monte Carlo sampling, to handle and utilize uncertain data.

### Here's what we found...

- > Intra-object statistics
  - For 34 objects. information on individual regions (Fig. 1).
- Population statistics
  - Shock velocity and density electron distribution (Figs. 2, 3).
- SNR evolution
  - Clear anticorrelation between velocity and age and weak correlation between velocity and density, in agreement with models of SNR evolution (Figs. 4, 5).
  - Age is the driving factor of shock velocity for optically emitting SNRs.
